## Main Idea

Our strategy exploits the "Inventory-Push Alpha" within the 2026 Canadian defense sector, where record-high backlogs are currently trapped by global supply chain bottlenecks. We identify Global Tier 1/2 Suppliers[1] (*the leaders*) whose stock price movements act as the leading indicator for the Canadian Prime Contractors (*the followers*). When a global supplier breaks out on high volume, it signals a resolution of component shortages, providing a statistically significant 5-to-60 day "early warning" that the Canadian follower is about to clear its backlog and recognize trapped revenue. We capture this information-diffusion lag by going long the Canadian follower and hedging out the market and tech-sector exposure using ETFs to isolate pure supply-chain convergence alpha. We are not just betting on the government contract; we are betting on the industrial reality of fulfillment. We monitor the 'leaders' in the supply chain to validate the 'followers' in our portfolio.

## Economic Hypothesis

The information diffusion gap and revenue recognition bottleneck are the two pillars of our strategy resting on Canada's first-ever Defense Industrial Strategy (DIS). The DIS set a target of 70% of defense contracts to be awarded to Canadian firms and boost defense industry revenue by 240%[2]. The scope for primary companies for this strategy is therefore Canadian markets; meanwhile, for the Tier 1 and 2 companies, the leaders, it is global markets.

As of March 2026, the follower segment collectively has on average USD $3.2B of backlog, with an average backlog ratio[3] of 2.4, meaning that these companies have almost 2.5 years of work already sold but not yet finished. In the 2026 defense sector, "Revenue Recognition" for Canadian Prime contractors, the followers, is physically gated by their global Tier 1 and Tier 2 suppliers. In a post-2025 world of supply chain fragility, record backlog[4] is a liability until their suppliers' signal "Clearance." Under IFRS 15 (Revenue from Contracts with Customers), Canadian defense firms generally recognize revenue based on "Performance Obligations" or "Milestone Completion."[5] So if the follower company cannot get the specific components from their suppliers (leader), they cannot reach the milestone, hence cannot recognize the revenue. The contract stays in the backlog instead of moving to the income statement. We exploit this gap by tracking the signal of the leader who would recognize the revenue when they work on or complete the contract and have it reflected in their stock price. The *Inventory-Push Alpha* exists because a breakout in the stock price of a global supplier (the leader), who sits at the start of the production cycle, is a statistically significant leading indicator that the bottleneck has cleared.

[2] Canada, Department of National Defence, *Security, Sovereignty and Prosperity*.
[3] Backlog ratio = Total backlog / Average Annual Revenue; for defense portion, the backlog ratio is 1.03; Refer to Appendix B
[4] Please refer to Appendix B for most recent data on backlogs
[5] International Accounting Standards Board, *IFRS 15: Revenue from Contracts with Customers* (London: IFRS Foundation, 2014), https://www.ifrs.org/issued-standards/list-of-standards/ifrs-15-revenue-from-contracts-with-customers/.

This signal allows us to front-run the follower's "revenue beat" 30–60 days before their quarterly earnings report.

## Implementation

The strategy begins by defining a defense-focused investment universe composed of approximately 30 companies. First, we select 10 high-conviction Canadian defense firms that represent the follower subgroup. For each Canadian prime contractor, we identify between one and three publicly traded global suppliers that provide critical technologies, components, or materials within their supply chain, representing our potential leaders. This structure produces an initial universe of roughly 30 companies and enables the analysis of lead-lag relationships between upstream suppliers and downstream Canadian defense firms. The universe is reviewed and updated monthly to incorporate newly relevant firms or supply-chain developments.

The core analytical component of the strategy involves detecting predictive lead-lag relationships between leaders and followers. Using return data over a rolling historical window of approximately two to three years, correlations are calculated between leader and follower returns across several return windows. Each return window corresponds to a different economic horizon that may reflect how information propagates through the defense supply chain.

Short return windows (intraday to approximately two weeks) capture rapid information diffusion, such as supplier announcements, earnings surprises, or analyst revisions. Medium return windows (one to three months) reflect slower adjustments within the supply chain, including order revisions, production updates, or changes in forward earnings expectations. Finally, longer return windows (six to twelve months) capture structural developments such as procurement cycles, defense budget allocations, or long-term contract implementation.

For each follower, the model evaluates correlations with every leader (Tier 1 and Tier 2 suppliers), across different return windows and multiple lags[6]. The lag represents the estimated delay between price movements in the leader and the subsequent response in the follower. The model identifies the lag that produces the strongest statistically significant relationship for each leader-follower pair. Relationships are retained only if the correlation is economically meaningful and statistically significant based on standard hypothesis tests. Appendix C provides a detailed description of the statistical methodology used in this selection process. The mosaic theory approach is used to verify economic significance using annual reports and news releases from the two companies. This filtering stage produces a shortlist of leader-follower relationships that demonstrate consistent predictive structure.

The strategy then monitors the selected leader securities for real-time signals that may indicate an upcoming price movement in their associated follower. Trading signals are generated using a momentum confirmation rule based on exponential moving averages (EMAs) applied to the leader's price series. The EMA parameters are calibrated relative to the identified return window

[6] The leader return series is shifted forward relative to the follower

and lag structure of each leader-follower relationship. When the leader's price begins trading significantly above its EMA, this is interpreted as abnormal positive momentum. For our research in building this strategy, we have established that threshold to be 20% above EMA. In response, the strategy initiates a long position in the corresponding follower, anticipating that the follower will respond to the leader's price movement after the estimated lag period.

The expected holding period for each trade is determined by the empirically observed lag between the leader and follower. For example, if the strongest predictive relationship occurs at a lag corresponding to approximately one month, the strategy expects the follower's response to materialize within that time window. If the predictive relationship occurs at longer economic horizons, positions may be held for a correspondingly longer duration. Positions are monitored continuously and are typically closed once the predicted lag period has elapsed or if the signal weakens. The constraint on this parameter is less than equal to 90 days since the benefits of information diffusion could very well be lost after that time. Trades may also be exited earlier if predefined profit targets are reached or if loss limits are triggered, allowing the strategy to capture gains while maintaining disciplined downside risk control. This will be discussed further in risk management section of the report.

Capital allocation within the strategy is intentionally conservative. Only a fraction of total capital is deployed into active positions at any given time. We optimize the weights of the security using Treynor-Black model, this weight becomes the upper limit. The risk of moving the market against us is mitigated by making sure our order size is less than equal to 10% of the Average Daily Volume (ADV). The order would be the lower of the two measures. At all times, we keep 10% of the total capital available for tactical strategies and another 10% for liquidity and risk control. This structure allows the strategy to absorb short-term volatility without forcing premature position liquidation.

## Risks

The strategy faces two primary risks that investors should consider: sector-level market exposure, which could introduce unintended systematic returns, and model and signal risk, which relates to whether the identified supply chain relationships reflect genuine economic linkages or simply statistical noise.

Although the strategy seeks profit from relative information advantages within the defense supply chain, broad sector movements could still contaminate returns. To isolate the supply chain lag alpha, the portfolio incorporates a sector-level hedge using ETFs, particularly iShares U.S. Aerospace & Defense (XAD.TO) and Global X Defense Tech Index ETF (SHLD.TO). The hedge ratio is estimated by regressing the long portfolio's returns against XAD.TO ETF, with the resulting beta used to size a short position in the ETF.

The exit point risk is also managed by predetermining the target profit, this is obtained by the performance of the leader stock. Once we see the peak and trough of the segments[7] we estimate the % profit we can expect and then take 90% of that profit. The reason we are not setting our target as 100% of the potential profit is because the volatility is higher near the peak.

Beyond sector exposure, the strategy also faces model and signal risk. Since the strategy relies on statistical relationships between supplier and contractor returns, there is a risk that observed correlations may arise from statistical noise or temporary market conditions rather than persistent economic relationships. To mitigate signal risk, all indicators undergo a multi-stage econometric validation. We first apply Augmented Dickey-Fuller (ADF) tests to ensure the stationarity of return series, preventing spurious correlations. Subsequently, we utilize bivariate cross-correlation analysis to quantify the lead-lag relationship between supplier and prime across staggered time-windows. Statistical significance is rigorously confirmed through t-statistics and p-values, ensuring that only persistent economic linkages, rather than transient market noise, inform our capital allocation. Only relationships meeting predefined thresholds for correlation strength and statistical significance are retained, and the analysis avoids overlapping return windows, which can artificially inflate statistical significance. To ensure the strategy's robustness against historical noise, we employ out-of-sample (OOS) testing, withholding 33% of the most recent 2024–2026 dataset as a clean 'unseen' environment to verify that the identified lead-lag signals persist outside of the initial model optimization. Finally, the strategy employs continuous back testing and signal monitoring, periodically re-evaluating historical relationships using rolling datasets to ensure that predictive structures remain stable over time, with signals that deteriorate or lose statistical significance removed from the trading universe.

## Liquidity and Capital Considerations

The strategy is designed to operate within a universe of publicly traded Canadian defense contractors that maintain strong market liquidity sufficient for institutional trading. These firms are among the larger and more established players in the domestic defense sector, with consistent daily trading volume supported by their inclusion in major Canadian equity indices. The global Tier 1 and Tier 2 suppliers, while not directly traded, serve as leading indicators whose price movements are monitored to anticipate forthcoming moves in the Canadian primary contractors. As a result, all executed positions are concentrated in highly liquid Canadian equities, and moderate to large position sizes can typically be established without materially impacting market prices.

Liquidity constraints are further managed through conservative position sizing and staggered entry timing as discussed earlier[8]. Trades are initiated shortly after signal confirmation and distributed across multiple executions where necessary. With the strategy focus on directional

[7] Measure returns from the first day of signal to 5 days, 2 weeks, 30/60/90 days. Returns are measured in $T+n$ intervals to capture the diffusion of information from leader to

.

[8] Please refer to the last paragraph under Implementation section

long positions in individual equities rather than leveraged derivatives, market impact and transaction costs remain manageable under typical trading conditions.

Capital deployment is structured to prioritize stability and scalability. At any given time, approximately 10% of total capital is allocated to active positions, with the remainder held as reserve liquidity and a buffer against short-term volatility. This ensures that temporary drawdowns do not force premature liquidation of positions. Within the active risk budget, individual positions are sized using a limit-based approach to prevent concentration risk. This allows the strategy to maintain diversified, concurrent exposures across multiple supplier-contractor pairings, capturing alpha from independent segments of the defense supply chain.

The strategy offers two clear pathways to scalability. As additional statistically significant supplier-contractor relationships are identified, the number of concurrent positions can expand accordingly. Additionally, because the strategy trades liquid equities rather than niche instruments, position sizes can scale alongside growth in total capital. Under these conditions, the strategy can deploy well above the $10 million threshold typically associated with small hedge fund strategies, while maintaining diversification across multiple supply chain signals.

## Analysis of Strategy Prospects

The lead-lag correlation framework used in our strategy identifies supplier-contractor relationships where supplier returns systematically preceded movements in downstream defense contractors. Across the analyzed universe, numerous statistically significant relationships were identified spanning multiple return horizons and lag windows.

Results show that meaningful correlations persist even when excluding co-movements (lag = 0). Within the one-month return horizon, the average correlation between suppliers and contractors reached 0.231 for lag windows between 15-29 trading days, based on 27 statistically significant relationships. Similarly, within two-week return windows, correlations averaged 0.195 for the same lag structure, supported by 35 relationships.

The signal becomes even stronger with longer horizons. Within three-month return windows, the average correlation reached 0.380 for lags between 15-29 trading days. The presence of statistically significant correlations across multiple lag windows suggests that information contained in supplier returns may propagate gradually through the supply chain rather than being immediately incorporated into contractor equity prices. (Appendix D: Lead-Lag Correlation Matrix)

One illustrative example involves the relationship between ATI and Bombardier. ATI produces titanium and nickel alloys widely used in aircraft structures and engines, Bombardier jets, making it an upstream supplier within the aerospace production network. The lead–lag analysis identifies a statistically significant relationship between the two firms, with a one-month return correlation of approximately 0.32, a lag of roughly five trading days, and a t-statistic of 9.3,

indicating a strong predictive relationship between supplier and contractor returns. This statistical signal places the pair on the monitoring list.

On May 1, 2025, ATI traded 21.2% above its exponential moving average, triggering the supplier momentum signal. We initiated a long position in Bombardier (BBD-B.TO) at its close of $82.54. To establish our profit objective, we monitored ATI's trajectory through its local peak on July 30th, where it reached $94.24, representing a gross leader return of 51.4%. Applying our 90% Profit Rule to this move, we derived a target return of 46.3% for our Bombardier position. This resulted in a calculated exit threshold of $120.75 ($82.54 × 1.463). On July 30th Bombardier's price had already smashed this threshold, the closure on the day was $162.64. By liquidating at this point we receive returns of nearly 100%. Thus, fulfilling our strategy's mandate: capturing the vast majority of the "diffusion" alpha while systematically insulating the fund from the heightened volatility and unhedged drawdown risk that typically characterizes the final, exhausted phase of a sector breakout.

It is critical to distinguish between our Signal Lag Constraint and our Dynamic Holding Period. Our model enforces a maximum 90-day lag between a leader's breakout and a follower's entry to ensure the information diffusion remains economically relevant. Conversely, the actual duration of a trade is determined by the leader's 'peak-to-trough' cycle. In the ATI-Bombardier case study, the leader's expansion phase lasted approximately 90 days; because this fell within our 90-day diffusion threshold, the signal remained valid. We exited the position on July 2, 2025, not because of a time-limit, but because the follower reached our 90% profit target derived from the leader's peak performance.

While this single example does not constitute a full back test, it illustrates how statistically identified supplier signals may translate into profitable trades in downstream contractors. (Appendix E: BBD-B and ATI One Month Returns). Therefore, while correlation alone does not guarantee profitability, the persistence of statistically significant lead-lag relationships across multiple horizons suggests that supplier returns contain information that can be systematically exploited if the signals persist.

## Conclusion

The Inventory-Push Alpha strategy provides a statistically rigorous framework for capturing the information-diffusion lag within the 2026 Canadian defense supply chain. By identifying global "leader" signals to predict revenue recognition for Canadian "followers," the strategy transforms record-high backlogs from a liability into a systematic source of alpha. Through disciplined risk management, including beta-neutral hedging and the 90% Profit Rule, the portfolio is engineered to deliver stable, scalable returns while insulating investors from broader sector volatility.

## APPENDIX C: LEADER-FOLLOWER STATISTICAL PAIRING AND IDENTIFICATION

For each potential Leader-Follower pair, the model evaluates predictive relationships using cross-correlation analysis across multiple return windows and lag structures. First, returns are computed using several return windows, representing different economic time horizons. These windows include short-term intervals (intraday to two weeks), medium-term intervals (one to three months), and long-term intervals (six to twelve months). Using multiple return windows allows the model to capture different speeds of information transmission within the defense supply chain. For each return window, the model calculates cross-correlations between the leader and follower return series across multiple lags, where the leader series is shifted forward in time relative to the follower. A positive lag indicates that movements in the leader precede movements in the follower. Each potential relationship is evaluated using standard statistical measures, including correlation coefficients, t-statistics, and p-values. Prior to analysis, return series are tested for stationarity to ensure statistical validity. Relationships are retained only if they satisfy several statistical and economic filters:

- The lag must be positive (>0), indicating predictive movement rather than simultaneous co-movement.
- The correlation must be at least 0.2, indicating a meaningful relationship.
- The t-statistic must exceed 2, suggesting statistical reliability.
- The p-value must be below 0.05, meeting conventional significance thresholds.
- The size of the lag, proportional to the return window, must be considered when analyzing the t-statistic and p-value due to overlapping return bias.

Among all candidate relationships, the model selects the combination of leader, follower, return window, and lag that produces the strongest statistically and economically meaningful predictive structure.

Sample Output for Lead-Lag Analysis: Comparing MDA Space to all Tier 1/2 Suppliers

```
Lead-Lag Analysis for MDA.TO:

--- two_week_returns ---
HON | Lag: -4 | Corr: 0.3013 | T-stat: 8.55 | P-value: 0.0000 | N: 735 | Significant: True
TDY | Lag: 0 | Corr: 0.2545 | T-stat: 7.14 | P-value: 0.0000 | N: 739 | Significant: True
PH | Lag: 24 | Corr: 0.2291 | T-stat: 6.28 | P-value: 0.0000 | N: 715 | Significant: True
ATI | Lag: 24 | Corr: 0.2086 | T-stat: 5.70 | P-value: 0.0000 | N: 715 | Significant: True
RR.L | Lag: 6 | Corr: 0.2069 | T-stat: 5.71 | P-value: 0.0000 | N: 730 | Significant: True
LDO.MI | Lag: 1 | Corr: 0.1955 | T-stat: 5.40 | P-value: 0.0000 | N: 735 | Significant: True
LHX | Lag: 1 | Corr: 0.1944 | T-stat: 5.38 | P-value: 0.0000 | N: 738 | Significant: True
CRS | Lag: 20 | Corr: 0.1882 | T-stat: 5.13 | P-value: 0.0000 | N: 719 | Significant: True
LMT | Lag: 0 | Corr: 0.1832 | T-stat: 5.06 | P-value: 0.0000 | N: 739 | Significant: True
3402.T | Lag: -23 | Corr: 0.1803 | T-stat: 4.81 | P-value: 0.0000 | N: 689 | Significant: True
HWM | Lag: 20 | Corr: 0.1735 | T-stat: 4.72 | P-value: 0.0000 | N: 719 | Significant: True
SAF.PA | Lag: -24 | Corr: 0.1517 | T-stat: 4.09 | P-value: 0.0000 | N: 712 | Significant: True
HXL | Lag: 0 | Corr: 0.1432 | T-stat: 3.93 | P-value: 0.0001 | N: 739 | Significant: True
HO.PA | Lag: 5 | Corr: 0.1238 | T-stat: 3.37 | P-value: 0.0008 | N: 731 | Significant: True
RTX | Lag: 22 | Corr: 0.1187 | T-stat: 3.20 | P-value: 0.0015 | N: 717 | Significant: True
RHM.DE | Lag: 2 | Corr: 0.1132 | T-stat: 3.08 | P-value: 0.0021 | N: 734 | Significant: True
```

In this case, we would shortlist the leader-follower pair (PH, MDA) equipped with a two-week return window and a lag of 24 days.

NOTE: all other return windows (intraday, one-month, three-month, etc.) in the above screenshot are omitted for simplification, but are all considered and outputted from the model.
